## ABSTRACT

Carbon quantum dots (CQDs) were simply blended with platinum salts (K<sub>2</sub>PtCl<sub>4</sub> and K<sub>2</sub>PtCl<sub>6</sub>) and converted into a hydrogen-evolution co-catalyst *in situ*, wherein Pt salts were dispersed on the surface of CQDs under photoirradiation of an aqueous solution of NADH (an electron and proton source) and 2-phenyl-4-(1-naphthyl)quinolinium ion (QuPh<sup>+</sup>–NA) employed as an organic photocatalyst. The co-catalyst (CQDs/Pt) exhibits similar catalytic reactivity in H<sub>2</sub> evolution as that of pure Pt nanoparticles (PtNPs) although the Pt amount of CQDs/Pt was only 1/200 that of PtNPs previously reported. CQDs were able to capture the Pt salt acting as Pt supports. Meanwhile, CQDs act as electron reservoir, playing an important role to enhance electron transfer from QuPh<sup>+</sup>–NA to the Pt salt, which was confirmed by kinetic studies, XPS and HRTEM.

## 1. Introduction

Hydrogen (H<sub>2</sub>) is regarded as a clean fuel of the next generation because of its high energy density per weight, environmentally benign properties of nonemission of greenhouse gas and other harmful chemicals after burning [1–14]. Typically, a photocatalytic H<sub>2</sub>-evolution system, which is an essential part of artificial photosynthesis, is composed of a sacrificial electron donor, a photocatalyst with long-lived charge-separated state upon photoexcitation and an H<sub>2</sub>-evolution catalyst [8,15–19]. Up to date, one of the most efficient catalyst used for H<sub>2</sub> evolution is Pt nanoparticles (PtNPs), because Pt has a low over potential for proton reduction to evolve hydrogen [19,20]. However, due to the scarcity and high cost, the wide use of PtNPs is impeditive. Consequently, it is highly desired to reduce the amount of Pt in the catalytic system. A great deal of efforts have been devoted to prepare PtNPs as small as possible to reduce the amount of Pt. PtNPs with size of a few nanometers have been successfully synthesized on a supporting material such as Pt/C [21–31]. Their catalytic activities are greatly influenced by the particle size, surface structure, and the metal/support interfaces [32–37]. At the same time, PtNPs loaded on special position of support were prepared to reduce the amount of Pt and to improve the photocatalytic activities [38,39]. Recently, a new way to form H<sub>2</sub>-evolution catalysts from metal salts inside the mesopores of silica–alumina loading photosensitizers with

long-lived electron-transfer (ET) state has been developed, wherein the metal salts were reduced *in situ* in the reaction solution to form smaller size metal nanoparticles [40]. Although the lifetime of the ET state could be prolonged by supporting donor–acceptor linked dyads on mesoporous silica–alumina, the H<sub>2</sub> yield still needs to be improved. To some extent, it may be due to the poor electron-transfer ability of mesoporous silica–alumina itself, which prohibits the electron transfer between the photocatalyst and H<sub>2</sub>-evolution catalysts [40].

Fortunately, carbon quantum dots (CQDs), as a rising star in nanocarbon family, may be a good candidate to serve as a support because of their unique electron-reservoir ability, efficient electron transfer, excellent water dispersibility, chemical stability, nano size, abundant/inexpensive nature and nontoxicity [41–44]. Owing to these advantages, CQDs have previously decorated PtNPs to improve their photocatalytic H<sub>2</sub> production [45–47]. The process of PtNPs' preparation is also difficult to be controlled, causing a loss of Pt.

Herein, in order to reduce Pt content and to make good use of Pt in the photocatalytic H<sub>2</sub> production, CQDs/Pt co-catalyst were *in-situ* prepared from CQDs and little amount of Pt salts (K<sub>2</sub>PtCl<sub>4</sub> and K<sub>2</sub>PtCl<sub>6</sub>). Pt species can be deposited on CQDs to form CQDs/Pt co-catalyst. The H<sub>2</sub> evolution activity with CQDs/Pt co-catalyst was examined in the system composed of 2-phenyl-4-(1-naphthyl)quinolinium ion (QuPh<sup>+</sup>–NA: photocatalyst) and dihydronicotinamide adenine dinucleotide (NADH: electron donor). The whole reaction scheme is depicted in Scheme 1. Kinetic studies, high-resolution transmission electron microscopy (HRTEM) images

and X-ray photoelectron spectroscopy (XPS) were used to confirm that CQDs as electron reservoir play an important role to enhance electron transfer from the organic photocatalyst (QuPh<sup>+</sup>-NA) to Pt salts.

## 2. Materials and methods

### 2.1. Materials

EDTA-2Na·2H<sub>2</sub>O, K<sub>2</sub>PtCl<sub>4</sub> and K<sub>2</sub>PtCl<sub>6</sub> were purchased from Sigma-Aldrich. 2-Phenyl-4-(1-naphthyl)quinolinium perchlorate (QuPh<sup>+</sup>-NA) was synthesized by the reported method [48]. Each buffer solution was prepared by addition of NaOH to an aqueous solution containing 50 mM of electrolyte (phthalate for pH 4.5, phosphate for pH 7.0 or 8.0, or boric acid /potassium chloride for pH 9.0) or 25 mM of carbonate for pH 10. All chemicals were used without further purification.

### 2.2. Preparation of CQDs from EDTA-2Na

EDTA-2Na·2H<sub>2</sub>O containing relatively stable carboxylate anions (COO<sup>-</sup>) was chosen as the precursor. After pyrolysis under low temperature, COO<sup>-</sup> can remain and thus render the CQDs soluble in water, and easily capture Pt cation. EDTA-2Na·2H<sub>2</sub>O (1.6 g) was calcined in a tube furnace at 350 °C for 2 h at a heating rate of 5 °C min<sup>-1</sup> in a N<sub>2</sub> atmosphere. The product was ground and dispersed in water (100 mL), and then centrifuged at a high speed (10,000 rpm) for 20 min. The upper brown dispersion was filtered with slow-speed quantitative microporous filter paper (0.25 μm) to remove the non-fluorescent deposit. The filtrate was dialyzed with MD34 (3500 Da) dialysis tube for 48 h to remove the remaining salts and small fragments. Pure luminescent CQDs powder was obtained by drying the concentrated solution at 60 °C for 24 h.

### 2.3. Characterization of CQDs

High-resolution transmission electron microscopy (HRTEM) images were taken on a JEOL JEM-2100UHR microscope with an accelerating voltage of 200 kV. Further evidence for the composition of the product was inferred from X-ray photoelectron spectroscopy (XPS), using a Thermo Scientific ESCALAB 250Xi spectrometer equipped with a pre-reduction chamber. Fourier transform infrared (FT-IR) spectra were recorded on a Nicolet 6700 spectrometer. Raman spectroscopy was recorded using an Ar<sup>+</sup> ion laser at 514.5 nm (Renishaw in via 2000 Raman microscope, Renishaw plc, UK) to assess the graphitic structure of raw materials and products.

### 2.4. Photocatalytic hydrogen evolution

A mixed solution (2.0 mL) of an aqueous buffer (pH 4.5, 7.0, 8.0, 9.0 or 10) and MeCN [1:1 (v/v)] containing QuPh<sup>+</sup>-NA (0.22 mM), NADH (1.0 mM), CQDs, K<sub>2</sub>PtCl<sub>4</sub> or K<sub>2</sub>PtCl<sub>6</sub> was flushed with N<sub>2</sub> gas. The solution was then irradiated with a Xe lamp (Ushio Optical, Model X SX-UID 500X AMQ) through a color filter glass (Toshiba Glass UV-35) transmitting λ > 340 nm at room temperature. The gas in the headspace was analyzed using a Shimadzu GC-14B gas chromatograph (detector, TCD; column temperature, 50 °C; column, active carbon with 60–80 mesh particle size; carrier gas, N<sub>2</sub>) to quantify the evolved hydrogen.

### 2.5. Kinetic measurements

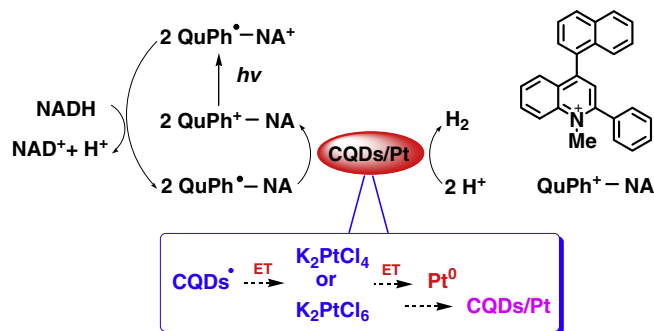

A mixed solution (2.0 mL) of a deaerated aqueous buffer (pH 7.0) and MeCN [1:1 (v/v)] containing QuPh<sup>+</sup>-NA (0.44 mM) and NADH (1.0 mM) was photoirradiated for 15 min with a Xe lamp through a color filter glass transmitting λ > 340 nm. Next, a deaerated aqueous solution containing CQDs, K<sub>2</sub>PtCl<sub>4</sub>, K<sub>2</sub>PtCl<sub>6</sub>, CQD/K<sub>2</sub>PtCl<sub>4</sub> or CQDs/K<sub>2</sub>PtCl<sub>6</sub> was added to the photoirradiated solution using a microsyringe with stirring. Rate constants of electron transfer from QuPh<sup>+</sup>-NA (obtained by one-electron reduction of QuPh<sup>+</sup>-NA) to the catalyst were determined from the decay of absorption at 510 nm due to QuPh<sup>+</sup>-NA, which was monitored using a Hewlett-Packard 8453 diode array spectrophotometer with a quartz cuvette (path length 10 mm) at 298 K.

## 3. Results and discussion

### 3.1. Characterization of CQDs

The uniformity of the as-synthesized CQDs is clearly shown in Fig. 1. The diameters of CQDs are centered at 2–3 nm from transmission electron microscopy (TEM) images. High-resolution TEM (HRTEM) images of CQDs show well-resolved lattice fringes with interplanar spacings of 0.20 nm, which are close to the (100) diffraction facets of graphite carbon. The Raman peaks centered at ~1334 and 1561 cm<sup>-1</sup> for the CQDs are attributed to the D and G bands of carbon materials representing the sp<sup>3</sup> and sp<sup>2</sup> carbon, respectively (see Supporting Information Fig. S1). The intensity ratio of the D and G bands (I<sub>D</sub>/I<sub>G</sub>) is a measure of the disorder extent, as well as the ratio of sp<sup>3</sup>/sp<sup>2</sup> carbons. The I<sub>D</sub>/I<sub>G</sub> ratio of CQDs is 0.7775, indicating that sp<sup>2</sup> hybridization C was much more than sp<sup>3</sup> hybridization C [49]. Therefore, the above results suggest that CQDs are composed of nanocrystalline cores of graphitic sp<sup>2</sup> carbon atoms, and it will benefit for the electron reservoir and efficient electron transfer [44].

The chemical compositions and structures of the CQDs were further investigated. X-ray photoelectron spectroscopy (XPS) measurements show that carbon (C1s, 283 eV), nitrogen (N1s, 398 eV), and oxygen (O1s, 530 eV) elements were contained in CQDs. The XPS spectrum of C1s from CQDs can be deconvoluted into three smaller peaks, which are ascribed to the following functional groups: sp<sup>3</sup> bonded carbon (C–C, 283.0 eV), sp<sup>2</sup> bonded carbon (C=C, 283.8 eV) and epoxy/hydroxyls (C–O, 286.4 eV) (Fig. 2) [50,51]. The O1s spectrum could be deconvoluted into three peaks of C=O (529.4 eV), C–O (530.3 eV) and chemisorbed oxygen (COOH) and/or bound water (533.6 eV) [52,53]. Elemental analysis also confirmed the composition of CQDs (C: 42.01%, H: 5.83%, N: 9.95%). In the fourier transform infrared spectroscopy (FT-IR) analysis of CQDs (see Supporting Information Fig. S2), the absorption bands from 1113 to 1263 cm<sup>-1</sup> are assigned to a C–O–C stretching and deformation vibrations, and those at 716, 851 and 1600 cm<sup>-1</sup> are characteristic of benzene ring. The residue peaks at 1329 cm<sup>-1</sup>

**Scheme 1.** Structure of QuPh<sup>+</sup>-NA and the overall catalytic cycle for photocatalytic hydrogen evolution.

Fig. 1. (a) TEM image of CQDs and (b) the corresponding distribution.

and  $998\text{ cm}^{-1}$  are assigned to O=C=O and C—OH stretching vibrations, respectively. Therefore, CQDs are graphite nanoparticles with oxygen-containing functional groups, which not only improve the water solubility but also provide “hands” to capture Pt salts via electrostatic force and van der Waals force.

### 3.2. Photocatalytic H<sub>2</sub> evolution of ratio-controlled CQDs with Pt salts (K<sub>2</sub>PtCl<sub>4</sub> and K<sub>2</sub>PtCl<sub>6</sub>)

CQDs and Pt salts (K<sub>2</sub>PtCl<sub>4</sub> and K<sub>2</sub>PtCl<sub>6</sub>) used as hydrogen-evolution co-catalysts were prepared by simple mixture. Fig. 3 shows the time courses of H<sub>2</sub> evolution under photoirradiation ( $\lambda > 340\text{ nm}$ ) of a mixed solution (2.0 mL) of KH<sub>2</sub>PO<sub>4</sub> buffers (pH 7.0) and MeCN [1:1 (v/v)] containing QuPh<sup>+</sup>-NA (0.22 mM), NADH (1.0 mM), various ratio of CQDs and Pt salts. QuPh<sup>+</sup>-NA efficiently absorbs the light at wavelengths longer than 340 nm as reported

previously, and NADH was used as a sacrificial electron donor, which can afford the stoichiometric amount of H<sub>2</sub> (2.0  $\mu\text{mol}$ ) [54]. Without QuPh<sup>+</sup>-NA, CQDs or Pt salts, no hydrogen evolution was observed from the mixed solution under the same reaction conditions. H<sub>2</sub> evolution with various ratios of CQDs and Pt salts were optimized as follows. When the weight ratio of CQDs/ K<sub>2</sub>PtCl<sub>6</sub> comes to 5:4 (CQDs: Pt = 15:4), the H<sub>2</sub>-evolution rate is higher than other ratios. The H<sub>2</sub> yield with co-catalyst (CQDs: K<sub>2</sub>PtCl<sub>6</sub> = 5:4) could come to 95%, which is calculated from the amount of NADH used in the reaction, wherein the stoichiometric amount (2.0  $\mu\text{mol}$ ) of H<sub>2</sub> was produced in the reaction with PtNPs under the same conditions. For co-catalyst of CQDs/K<sub>2</sub>PtCl<sub>4</sub>, the optimization ratio of CQDs and K<sub>2</sub>PtCl<sub>4</sub> was 3:2 (CQDs: Pt = 15:4). After irradiation the mixed solution with CQDs/K<sub>2</sub>PtCl<sub>4</sub> co-catalyst for 40 min, the amount of evolved H<sub>2</sub> reached 1.6  $\mu\text{mol}$  (80% yield) which is higher than that of CQDs/K<sub>2</sub>PtCl<sub>6</sub> co-catalyst (1.35  $\mu\text{mol}$ ).

**Fig. 3.** Time courses of hydrogen evolution under photoirradiation ( $\lambda > 340$  nm) of deaerated mixed solutions (2 mL) of  $\text{KH}_2\text{PO}_4$  buffers (pH = 7.0) and MeCN [1:1 (v/v)] containing  $\text{QuPh}^+\text{-NA}$  (0.22 mM), NADH (1.0 mM), various loadings of CQDs ( $4.7 \text{ mg L}^{-1}$ ,  $9.4 \text{ mg L}^{-1}$  and  $18.8 \text{ mg L}^{-1}$ ) and (a)  $\text{K}_2\text{PtCl}_6$  ( $7.29 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{mol L}^{-1}$ ). When the weight ratio of CQDs and  $\text{K}_2\text{PtCl}_6$  is 5:4, the mixed solution gives the best performance. (b)  $\text{K}_2\text{PtCl}_4$  ( $6.23 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{M}$ ). When the weight ratio of CQDs and  $\text{K}_2\text{PtCl}_4$  is 3:2 ( $\text{K}_2\text{PtCl}_4 = 6.23 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{M}$ , CQDs =  $9.4 \text{ mg L}^{-1}$ ), the mixed solution gives the best performance.

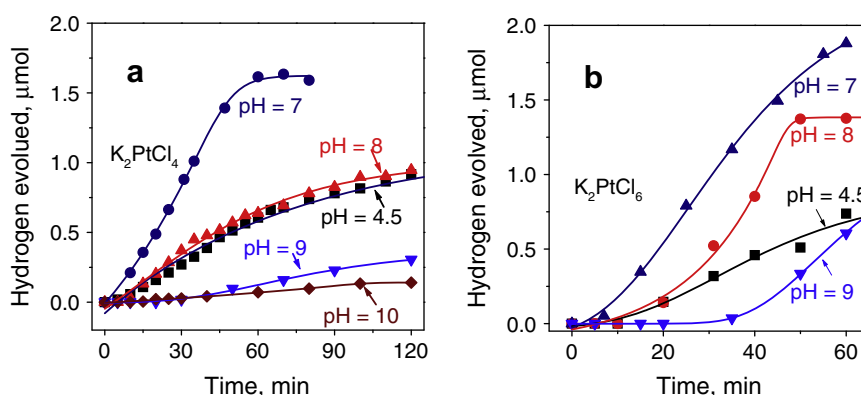

### 3.3. Photocatalytic $\text{H}_2$ evolution with CQDs/Pt salts under various pH conditions

The photocatalytic  $\text{H}_2$ -evolution experiments were performed with a mixture of an aqueous buffer and MeCN [1:1 (v/v)] containing  $\text{QuPh}^+\text{-NA}$  (0.22 mM), NADH (1.0 mM), CQDs ( $9.4 \text{ mg L}^{-1}$ ) and  $\text{K}_2\text{PtCl}_6$  ( $7.29 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{M}$ ) or  $\text{K}_2\text{PtCl}_4$  ( $6.23 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{M}$ ) under various pH conditions. Fig. 4 shows the amount of evolved  $\text{H}_2$  as a function of photoirradiation time at pH 4.5, 7.0, 8.0, 9.0 and 10. For CQDs/ $\text{K}_2\text{PtCl}_4$  co-catalyst, the amount of evolved  $\text{H}_2$  at pH 7.0 reached  $1.6 \text{ } \mu\text{mol}$  (80% yield) after 40 min, which is about twice of that at pH 4.5 and 8.0. The catalytic reactivity of CQDs/ $\text{K}_2\text{PtCl}_6$  co-catalyst for photocatalytic  $\text{H}_2$  evolution was also examined under various pH conditions. Fig. 4b shows the time course of photocatalytic  $\text{H}_2$  evolution using CQDs/ $\text{K}_2\text{PtCl}_6$  as the hydrogen-evolution catalyst under the same reaction conditions as the case of CQDs/ $\text{K}_2\text{PtCl}_4$ . Compared with CQDs/ $\text{K}_2\text{PtCl}_4$  co-catalyst, CQDs/ $\text{K}_2\text{PtCl}_6$  co-catalyst shows more efficient  $\text{H}_2$  evolution at pH 7.0 and 8.0, respectively. After irradiation of the mixed solution with CQDs/ $\text{K}_2\text{PtCl}_6$  co-catalyst at pH 8.0 for 50 min, the amount of evolved  $\text{H}_2$  was  $1.4 \text{ } \mu\text{mol}$  (70% yield). Unlike conventional  $\text{H}_2$  evolution systems which exhibit better performance under acid conditions, the CQDs/Pt salt can act as good  $\text{H}_2$  evolution catalyst under neutral or weakly alkaline conditions. Under such conditions, carboxylic acid moieties ( $-\text{COOH}$ ) contained in CODs are converted into carboxylate anion ( $-\text{COO}^-$ ), which can capture Pt

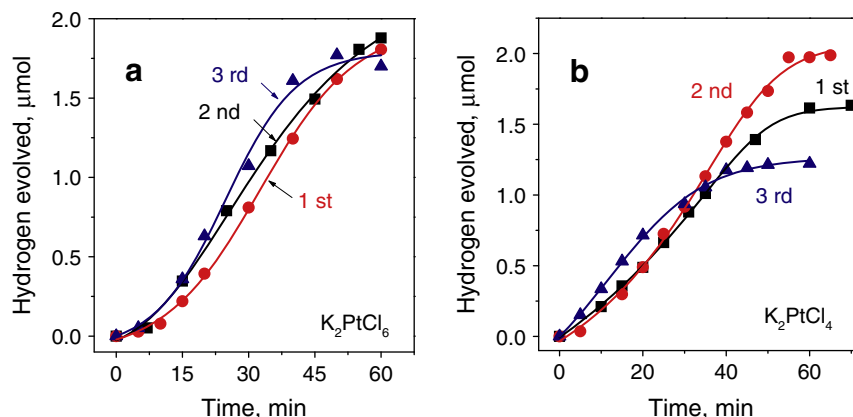

cation easily on the surface of CQDs and synergistically catalyze the hydrogen evolution.

### 3.4. Repetitive photocatalytic $\text{H}_2$ evolution with CQDs/Pt salts

The robustness of the CQDs/Pt co-catalyst was scrutinized by the repeated use in the photocatalytic  $\text{H}_2$  evolution. The photocatalytic  $\text{H}_2$  evolution was repetitively performed by photoirradiation ( $\lambda > 340$  nm) of a deaerated mixed solution (2.0 mL) of a  $\text{KH}_2\text{PO}_4$  buffer (pH 7.0) and MeCN containing NADH (1.0 mM),  $\text{QuPh}^+\text{-NA}$  (0.22 mM), CQDs ( $9.4 \text{ mg L}^{-1}$ ) and Pt salts ( $15 \text{ } \mu\text{M}$ ). After each catalytic reaction, a concentrated solution of NADH was added to the solution (twice). Time courses of the  $\text{H}_2$  evolution are shown in Fig. 5. In the case of the photocatalytic reaction with CQDs/ $\text{K}_2\text{PtCl}_6$  for the first time, the total amount of evolved  $\text{H}_2$  reached  $1.8 \text{ } \mu\text{mol}$  in 1 h. During this time,  $\text{K}_2\text{PtCl}_6$  was reduced by CQDs to form Pt metal species that act as an actual  $\text{H}_2$  evolution catalysts. After 1st cycle, a concentrated solution of NADH was added to the solution, the reuse of the CQDs/ $\text{K}_2\text{PtCl}_6$  with photodeposited Pt species resulted in faster and more  $\text{H}_2$  evolution ( $1.9 \text{ } \mu\text{mol}$ ) in 1 h, even in the 3rd cycle. The faster  $\text{H}_2$ -evolution resulted from the removal of  $\text{K}_2\text{PtCl}_6$ , which partly disturbs  $\text{QuPh}^+\text{-NA}$  from the photoexcitation (vide infra). Thus, Pt species deposited on the CQDs act as the efficient  $\text{H}_2$ -evolution catalyst. Similarly, faster  $\text{H}_2$  evolution with CQDs/ $\text{K}_2\text{PtCl}_4$  in the 2nd cycle compared with the 1st cycle was also observed when NADH

**Fig. 4.** Time courses of evolved hydrogen under photoirradiation ( $\lambda > 340$  nm) of deaerated mixed solutions (2 mL) of aqueous buffers at various pH values and MeCN [1:1 (v/v)] containing  $\text{QuPh}^+\text{-NA}$  (0.22 mM), NADH (1.0 mM), CQDs ( $9.4 \text{ mg L}^{-1}$ ) (a)  $\text{K}_2\text{PtCl}_4$  ( $6.23 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{mol}$ ) with CQDs ( $9.4 \text{ mg L}^{-1}$ ); (b)  $\text{K}_2\text{PtCl}_6$  ( $7.29 \text{ mg L}^{-1}$ ,  $15 \text{ } \mu\text{M}$ ).

**Fig. 5.** Time courses of H<sub>2</sub> evolution in the repetitive photocatalytic reactions. H<sub>2</sub> evolution was examined by photoirradiation ( $\lambda > 340$  nm) of a deaerated mixed solution (2.0 mL) of a KH<sub>2</sub>PO<sub>4</sub> buffers (pH 7.0) and MeCN [1:1 (v/v)] containing QuPh<sup>+</sup>-NA (0.22 mM), NADH (1.0 mM), CQDs (9.4 mg L<sup>-1</sup>) and (a) K<sub>2</sub>PtCl<sub>6</sub> (7.29 mg L<sup>-1</sup>, 15  $\mu$ M) or (b) K<sub>2</sub>PtCl<sub>4</sub> (6.23 mg L<sup>-1</sup>, 15  $\mu$ M). The mixed solution of a KH<sub>2</sub>PO<sub>4</sub> buffers and MeCN [1:1 (v/v)] containing NADH was added to the reaction solution three times after each run.

(1.0 mM) was added as a sacrificial electron donor (Fig. 5b). At the 3rd cycle, the H<sub>2</sub> evolution rate at the initial 30 min was faster than that at the 1st and 2nd cycles. Unfortunately, the amount of evolved H<sub>2</sub> at the 3rd cycle could not reach as much as the amount at the 1st cycle.

### 3.5. H<sub>2</sub> evolution of CQDs/Pt salt under ultra-lower concentration

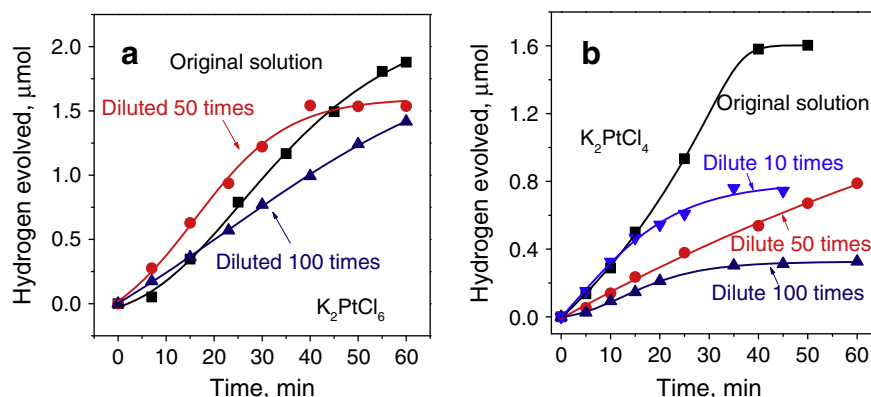

In order to reduce Pt content, the photocatalytic hydrogen evolution was performed by using low content of Pt salts and CQDs in a mixture of KH<sub>2</sub>PO<sub>4</sub> buffer (pH 7.0) and MeCN [1:1 (v/v)] containing QuPh<sup>+</sup>-NA (0.22 mM), NADH (1.0 mM), as shown in Fig. 6. When the original concentrations of K<sub>2</sub>PtCl<sub>6</sub> and CQDs were reduced to 1/50, the H<sub>2</sub> evolution rate became even faster than that with the original concentration (Fig. 6a), because the low content of K<sub>2</sub>PtCl<sub>6</sub> and CQDs resulted in more effective absorption of light by QuPh<sup>+</sup>-NA alone with less absorption by CODS/Pt. Further reduction of the concentration of CQDs and K<sub>2</sub>PtCl<sub>6</sub> to 1/100 of the original concentrations resulted in the slower H<sub>2</sub> evolution rate (Fig. 6a). In the case of CQDs/K<sub>2</sub>PtCl<sub>4</sub> co-catalyst, however, the amount of evolved H<sub>2</sub> was 1/4 and 1/8 of that with original concentration when the concentrations of K<sub>2</sub>PtCl<sub>4</sub> and CQDs were diluted to 1/50 and 1/100, respectively. Such a difference between K<sub>2</sub>PtCl<sub>6</sub> and K<sub>2</sub>PtCl<sub>4</sub> may result from the slower rate of electron transfer from QuPh<sup>+</sup>-NA, which is produced by photoinduced electron transfer from NADH to QuPh<sup>+</sup>-NA, to K<sub>2</sub>PtCl<sub>4</sub> than that to K<sub>2</sub>PtCl<sub>6</sub> (vide infra).

The amount of evolved H<sub>2</sub> with low concentrations of CQDs and Pt salts at pH 4.5, 7.0 and 8.0 were also examined (see Supporting Information Fig. S3). Compared with the original concentration of co-catalyst, both CQDs/K<sub>2</sub>PtCl<sub>4</sub> and CQDs/K<sub>2</sub>PtCl<sub>6</sub> are sensitive to pH condition and show better performance at pH 7. For the repetitive experiments, unfortunately, the amount of evolved H<sub>2</sub> at the 2nd and 3rd cycle could not reach as much as the amount at the 1st cycle (see Supporting Information Fig. S4).

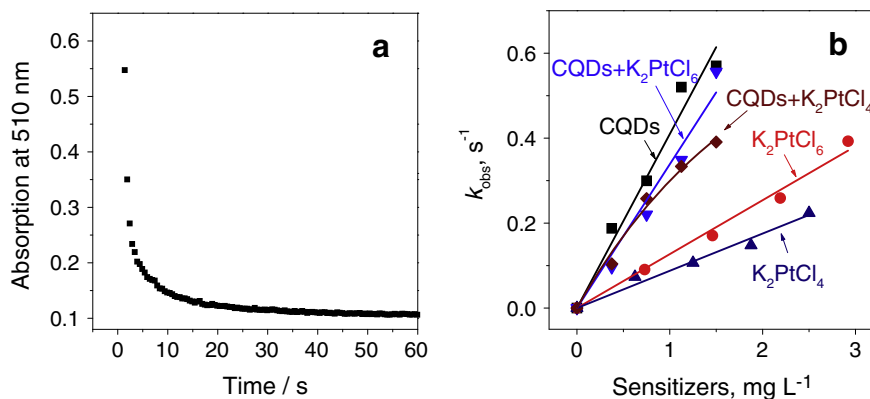

### 3.6. Electron transfer from QuPh<sup>+</sup>-NA to CQDs and Pt salts (QuPh<sup>+</sup>-NA to CQDs and Pt salt)

Rate constants of electron transfer ( $k_{\text{obs}}$ ) from QuPh<sup>+</sup>-NA to CQDs or Pt salts in a mixed solution of a KH<sub>2</sub>PO<sub>4</sub> buffers (pH 7.0) and MeCN [1:1 (v/v)] were determined by the UV-vis spectral change. This is the first example to determine the electron-transfer rate from a radical species to CQDs directly. An aliquot (2.0 mL) of QuPh<sup>+</sup>-NA (0.44 mM) was photoirradiated in the presence of NADH (1.0 mM) for several minutes to generate QuPh<sup>+</sup>-NA. Then, a small portion of an aqueous solution containing CQDs, Pt salts or their mixture was added to the mixed solution containing QuPh<sup>+</sup>-NA. For CQDs, the UV-vis absorption of QuPh<sup>+</sup>-NA at 510 nm obviously decrease (see Supporting Information Fig. S5), which indicates electron transfer from QuPh<sup>+</sup>-NA to CQDs.

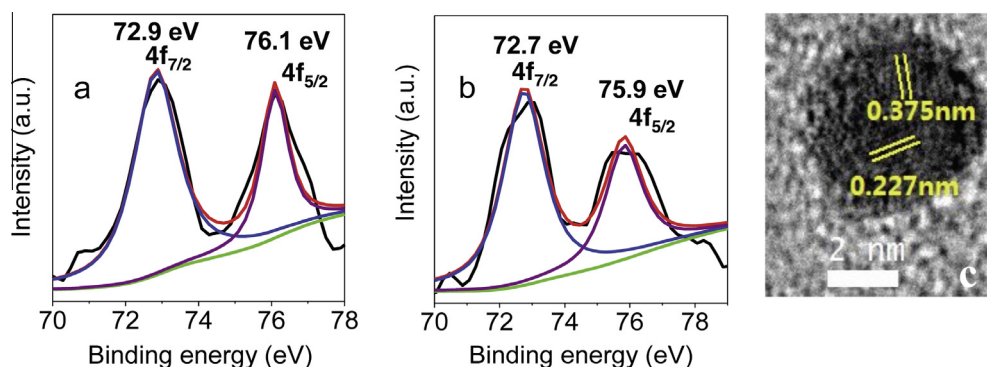

The rates of electron transfer ( $k_{\text{obs}}$ ) from QuPh<sup>+</sup>-NA to CQDs, K<sub>2</sub>PtCl<sub>4</sub>, K<sub>2</sub>PtCl<sub>6</sub> and CQDs/K<sub>2</sub>PtCl<sub>6</sub> obeyed first-order kinetics, and

**Fig. 6.** Time courses of hydrogen evolution under photoirradiation ( $\lambda > 340$  nm) of deaerated mixed solutions (2 mL) of KH<sub>2</sub>PO<sub>4</sub> buffers (pH = 7.0) and MeCN [1:1 (v/v)] containing QuPh<sup>+</sup>-NA (0.22 mM), NADH (1.0 mM), with lower concentration of Pt salt and CQDs at 298 K. (a) The original concentration of CQDs and K<sub>2</sub>PtCl<sub>6</sub> are 9.4 mg L<sup>-1</sup> and 7.29 mg L<sup>-1</sup> respectively,  $m_{\text{CQDs}}:m_{\text{K}_2\text{PtCl}_6} = 5:4$ ; (b) the original concentration of CQDs and K<sub>2</sub>PtCl<sub>4</sub> are 9.4 mg L<sup>-1</sup> and 6.23 mg L<sup>-1</sup> (15  $\mu$ M) respectively,  $m_{\text{CQDs}} : m_{\text{K}_2\text{PtCl}_4} = 3:2$ .

**Fig. 7.** (a) Decay time profiles of absorption at 510 nm due to QuPh<sup>+</sup>-NA in the electron transfer from QuPh<sup>+</sup>-NA to CQDs in a mixed solution (2.0 mL) of a deaerated aqueous buffer (pH 7.0) and MeCN [1:1 (v/v)]. QuPh<sup>+</sup>-NA was produced by photoirradiation of QuPh<sup>+</sup>-NA (0.44 mM) in the presence of NADH (1.0 mM). (b) Plots of the pseudo-first-order rate constants ( $k_{\text{obs}}$ ) for electron transfer from QuPh<sup>+</sup>-NA vs weight concentrations (CQDs, K<sub>2</sub>PtCl<sub>6</sub> and K<sub>2</sub>PtCl<sub>4</sub>).

**Fig. 8.** High-resolution XPS spectrum of Pt 4f from (a) the CQDs/K<sub>2</sub>PtCl<sub>6</sub> sample after H<sub>2</sub> evolved reaction; (b) the CQDs/K<sub>2</sub>PtCl<sub>4</sub> sample after H<sub>2</sub> evolved reaction; (c) High-resolution TEM (HRTEM) images of CQDs/K<sub>2</sub>PtCl<sub>4</sub> sample after H<sub>2</sub> evolved reaction.

the first-order rate constants increased linearly with increasing the amounts of CQDs and Pt salts. The electron-transfer rate constants ( $k_{\text{et}}$ ) were determined from the slopes of the linear plots of  $k_{\text{obs}}$  versus concentrations of CQDs and Pt salts in Fig. 7. The  $k_{\text{et}}$  values for CQDs were much larger than K<sub>2</sub>PtCl<sub>6</sub> and K<sub>2</sub>PtCl<sub>4</sub>, indicating that CQDs are a better electron acceptor than K<sub>2</sub>PtCl<sub>6</sub> and K<sub>2</sub>PtCl<sub>4</sub>. In such a case, electron transfer occurs from QuPh<sup>+</sup>-NA to CQDs firstly, followed by subsequent electron transfer to Pt salts in competition with direct electron transfer from QuPh<sup>+</sup>-NA to the Pt salts.

TEM images and XPS spectra of the CQDs/Pt after H<sub>2</sub> evolved reaction (Fig. 8) provide valuable information on the catalytically active species. High-resolution XPS spectrum of Pt 4f<sub>5/2</sub> and Pt 4f<sub>7/2</sub> from the CQDs/K<sub>2</sub>PtCl<sub>6</sub> sample exhibits binding energies of 76.1 eV and 72.9 eV, respectively (Fig. 8a), which is characteristic of Pt<sup>0</sup> [45], suggesting that electron transfer from QuPh<sup>+</sup>-NA to CQDs and K<sub>2</sub>PtCl<sub>6</sub> results in the reduction of K<sub>2</sub>PtCl<sub>6</sub> to Pt<sup>0</sup>. Compared with bulk metallic Pt<sup>0</sup> (Pt 4f<sub>7/2</sub>, 71.5 eV) [55,56], Pt 4f<sub>7/2</sub> in the CQDs/Pt exhibits a positively shifts of 1.4 eV, suggesting that the electronic environment surrounding the Pt atom is significantly changed due to strong interaction and intimate contact between Pt and graphene carbon. Similar results were also obtained for CQDs/K<sub>2</sub>PtCl<sub>4</sub> (Fig. 8b). In order to confirm the existence of Pt<sup>0</sup> in the photocatalytic H<sub>2</sub> evolution reaction, high-resolution TEM (HRTEM) images of CQDs/K<sub>2</sub>PtCl<sub>4</sub> sample after the H<sub>2</sub> evolution reaction were measured as shown in Fig. 8c. CQDs/Pt exhibit well-resolved lattice fringes with interplanar spacings of 0.375 nm and 0.227 nm, which are close to the (002) diffraction facets of graphite carbon [49] and the (111) diffraction facets of

pure Pt<sup>0</sup> [57], respectively. Compared with the lattice distance of original CQDs before reaction (0.20 nm), the presence of Pt in CQDs results in an increase in the lattice distance due to intimate contact between Pt<sup>0</sup> and CQDs.

#### 4. Conclusions

A highly active and robust catalyst composed of carbon quantum dots and Pt (CQDs/Pt) for H<sub>2</sub> evolution was obtained via an *in situ* facile method with an organic photocatalyst (QuPh<sup>+</sup>-NA), NADH, CQDs and Pt salts in an aqueous solution under photoirradiation. CQDs/Pt co-catalyst exhibited similar H<sub>2</sub> evolution activity as compared with PtNPs, although the Pt content of CQDs/Pt was only 1/200 of PtNPs. The formation of Pt<sup>0</sup> which has intimate contact with CODs was confirmed by the kinetic, HRTEM and XPS studies. The *in situ* formation of CQDs/Pt reported in this study paves a new way for design of efficient and robust H<sub>2</sub>-evolution catalysts.
